Dedicated to Theodore H. Geballe on the year of his 95th birthday
Edited by J.E. Hirsch, M.B. Maple, and F. Marsiglio

Table of Contents

I. Conventional Superconductors

- C1. Superconductivity in the elements, alloys and simple compounds
- C2. Superconductivity in the A-15 structure
- C3. Superconductivity in doped semiconductors
- C4. Superconductivity from insulating elements under high pressure
- C5. Superconductivity in graphite intercalation compounds
- C6. Superconductivity in the metallic elements at ultra-high pressures
- C7. Superconductivity in compressed hydrogen-rich materials: pressing on hydrogen
- C8. Pristine and Intercalated Transition Metal Dichalcogenides Superconductors
- C9. Chevrel phases: past, present and future
- C10. Magnetic superconductors
- C11. Superconductivity of Very Thin Films: the Superconductor-Insulator Transition
- C12. Superconductivity of magnesium-diboride

II. Possibly Unconventional Superconductors

- P1. Bismuthates: BaBiO₃ and related superconducting phases
- P2. Superconductivity in Alkali-doped C₆₀
- P3. Quaternary Borocarbides: Relatively high T_c intermetallic superconductors and magnetic superconductors
- P4. Superconductivity in Plutonium Compounds
- P5 Interface Superconductivity
- P6. Superconductivity in aromatic hydrocarbons
- P7. Superconducting doped topological materials
- P8. Superconductivity in Layered BiS₂-based compounds
- P9. Unstable and elusive Superconductors

III. Unconventional Superconductors

- U1. Unconventional Superconductivity in Heavy-Fermion Compounds
- U2. Organic Superconductors: the Bechgaard salts and relatives
- U3. Hole-Doped Cuprate High Temperature Superconductors
- U4. T' and infinite-layer electron-doped cuprates
- U5. Unconventional superconductivity in Sr₂RuO₄
- U6. Unconventional superconductivity in electron-doped layered metal nitride halides
- U7. Ferromagnetic Superconductors
- U8. Superconductivity of cobalt oxide hydrate, Na_x(H₃O)_zCoO₂ · yH₂O halides
- U9. Superconductivity in non-centrosymmetric superconductors
- U10. Iron-Based Superconductors: current status of materials and pairing mechanism
- U11. Superconductivity in Fe-chalcogenides

Physica C Special Issue on Superconducting Materials

Dedicated to Theodore H. Geballe on the year of his 95th birthday

Edited by J.E. Hirsch, M.B. Maple, and F. Marsiglio

What this talk is about

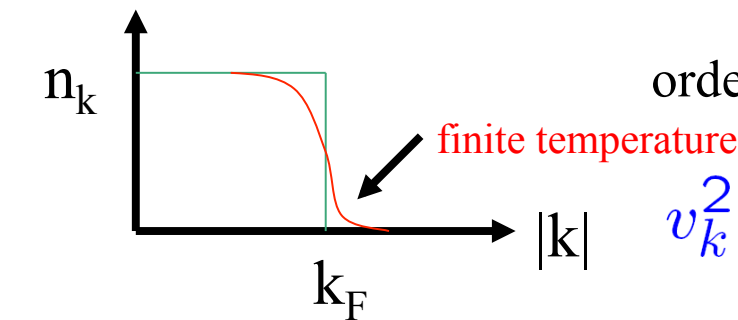

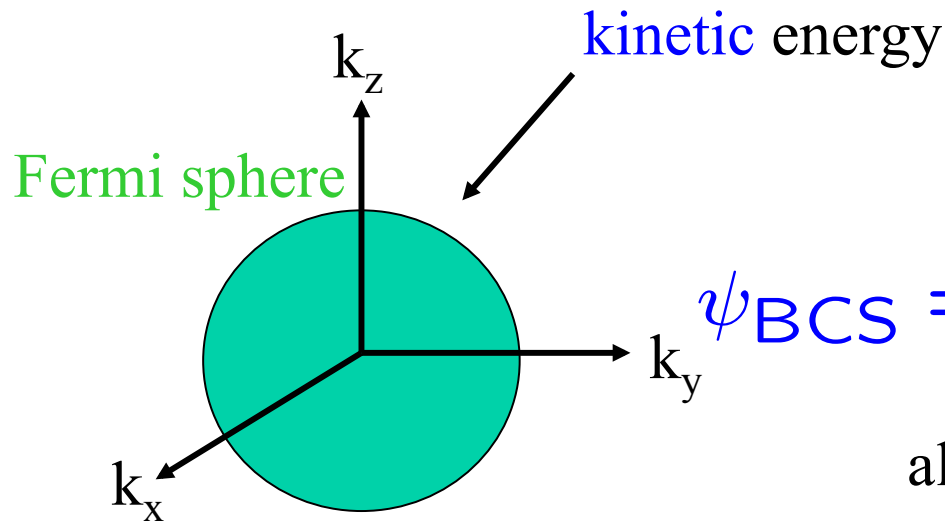

- 1) A 'lightning-quick' overview of Eliashberg Theory, as I would teach in a graduate course, for example.
- 2) Is there more, at least for the cuprates, for example?
- 3) The Dynamic Hubbard model --- is there more to Coulomb repulsions than μ^* ?
 - (i) conceptual look
 - (ii) DMFT solution
 - (iii) 2-site model
 - (iv) relation to high-Tc experiments (optics)

The conventional scenario: BCS

Electrons in solids

J. Bardeen L.N. Cooper J.R. Schrieffer

$$E_{\text{kin}} = 2 \sum \epsilon_k n_k$$

$$\psi_{\text{BCS}} = \prod_k (u_k + v_k c_{k\uparrow}^\dagger c_{-k\downarrow}^\dagger) |0\rangle$$

all k 's !! --- occupation is controlled by u_k and v_k .

order parameter (Δ_k) becomes non-zero, so, e.g.

$$v_k^2 = \frac{1}{2} \left(1 - \frac{\epsilon_k}{E_k} \right) \quad \text{where} \quad E_k = \sqrt{\epsilon_k^2 + \Delta_k^2}$$

$$\sim 1 \quad \text{for} \quad \epsilon_k < 0$$

$$\sim 0 \quad \text{for} \quad \epsilon_k > 0$$

It's all about pairs...

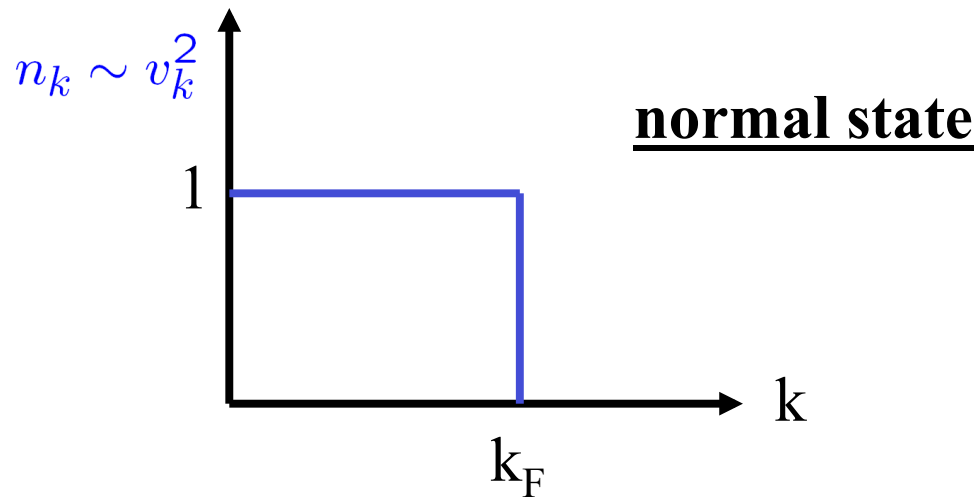

In Ogg's theory it was his intent
That the current keep flowing, once sent;
So to save himself trouble,
He put them in double,
And instead of stopping, it went.

George Gamow

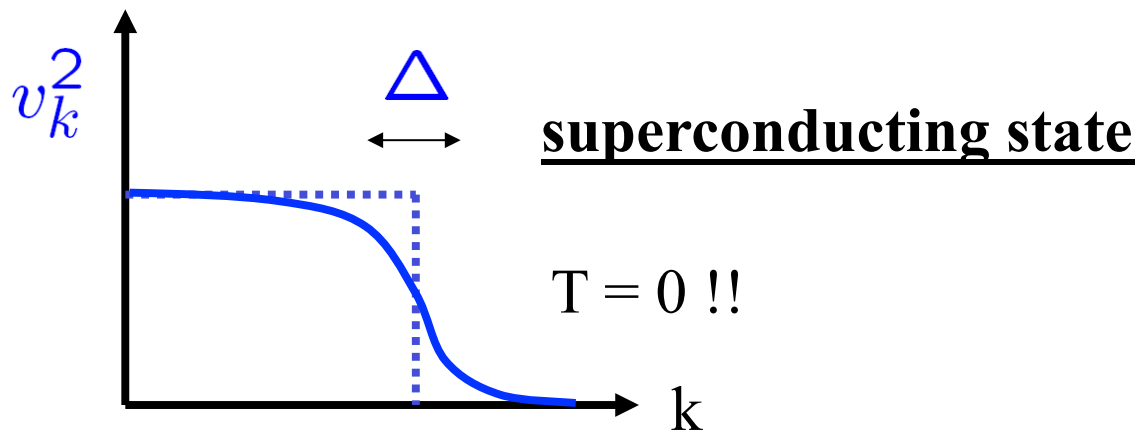

**Bose-Einstein Condensation of Trapped Electron
Pairs. Phase Separation and Super-
conductivity of Metal-Ammonia
Solutions**

RICHARD A. OGG, JR.
Department of Chemistry, Stanford University, California
March 2, 1946

...Cooper pairs

why sacrifice
kinetic energy ?

Ans: gain
potential energy

remember,
$$v_k^2 = \frac{1}{2} \left(1 - \frac{\epsilon_k}{\sqrt{\epsilon_k^2 + \Delta_k^2}} \right)$$

BCS formalism vs. Pairing Mechanism

$$\Delta = |V| \frac{1}{N} \sum_k \frac{\Delta}{2E_k}$$

Tc equation (useless)

$$\frac{2\Delta}{k_B T_c} = 3.53$$

Universality

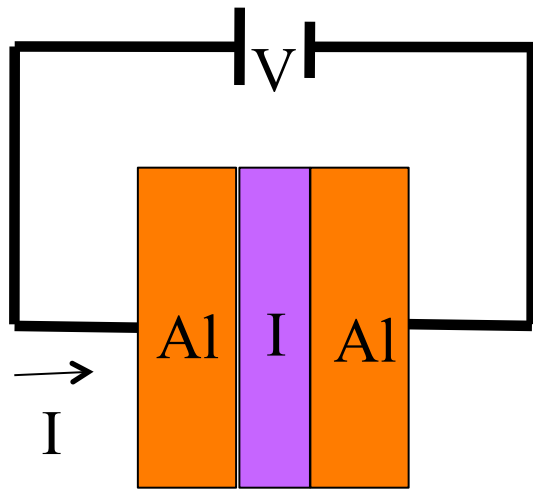

$$\frac{\Delta C}{\gamma T_c} = 1.43$$

Universality is wonderful

Universality is a curse!

B.L. Blackford and R.H. March, *Can. J. Phys.* **46**, 141 (1968)

Eliashberg Theory

- Extension of BCS formalism to include
S-STATE INSTABILITIES FOR RETARDED INTERACTIONS†

'Boss' buys tickets for military personnel

New York Yankees owner George Steinbrenner purchased 350 tickets for tonight's Game 2 of the NHL's Eastern Conference final between the Philadelphia Flyers and Tampa Bay Lightning for military personnel stationed at MacDill Air Force Base in Tampa. He also donated them to some of the families of servicemen and servicewomen fighting the war in Iraq. Steinbrenner also had donated more than 700 tickets for Game 2 of Tampa Bay's semifinals match-up against the Montreal Canadiens on April 25. Steinbrenner, who has a wife and three children, is the only owner in the league to have done this.

BCS formula up for tweaking

Stoops wants votes made public

By Steve Wieberg
USA TODAY

Architects of the Bowl Championship Series are close to drawing up a simpler and, they say, more fail-safe formula for selecting two teams to play for college football's national title.

The revisions won't be announced until next month. But Big East Conference Commissioner and outgoing BCS coordinator Mike Tranghese said Wednesday that they'll likely streamline a convoluted mathematical formula, essentially giving one-third weight to the Associated Press media poll, one-third to the USA TODAY/ESPN Coach Poll and a final one-third to a computer rating.

It no longer would include a separate strength-of-schedule rating, an escaping penalty for losses and probably nuses for "quality" wins. A final determination is awaiting analysis by outside mathematicians.

The modifications, Tranghese said, should avert a repeat of the messy split-championship outcome which saw Southern California ranked No. 1 in the voting polls but left out of the BCS' championship game because of lower computer and strength-of-schedule ratings.

the potential for offending opponents. "If you can't make it public, then you'd better throw the coaches' poll out," he said. "There needs to be more accountability. If there's not, then that

Dynamic Hubbard Model

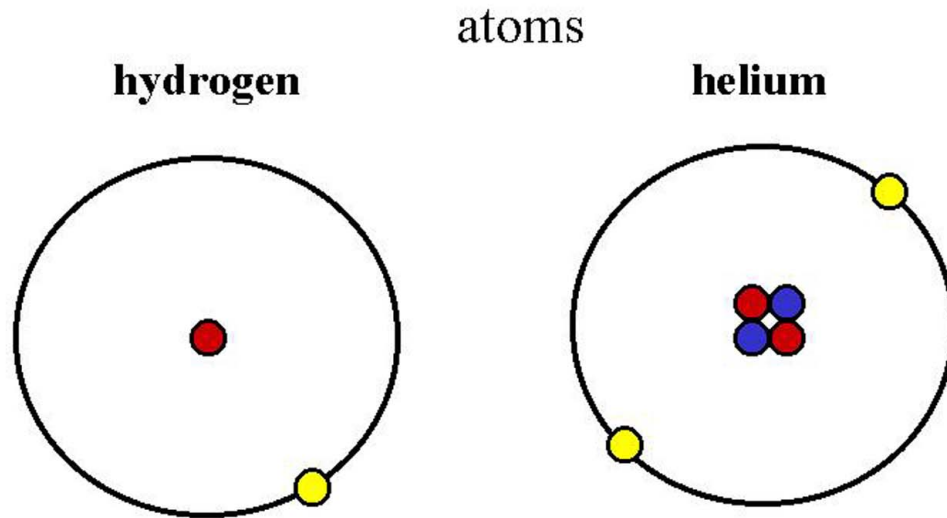

J. E. Hirsch

Department of Physics, University of California–San Diego, La Jolla, California 92093-0319

(Received 24 July 2001; published 26 October 2001)

...a parable involving the lowly Helium atom...

● proton (+) ● neutron ● electron (-)

Neutrons and protons are held together in the nucleus by the “strong” force, which has to overcome the electrical repulsion of the two positively charged protons in helium (and in more complex atoms too). Electrons are held around the atom by the electrical attraction between their negative charge and the positive charge of the protons in the nucleus.

Further Computations of the He Atom Ground State

Charles Schwartz *

*Department of Physics, University of California
Berkeley, California 94720*

Abstract

Recently reported computations have been extended to give ten more decimals of accuracy in the ground state energy of the Schrodinger equation for the idealized Helium atom. With the F basis - Hylleraas coordinates with negative powers and a logarithm of s - carried to the fiftieth order ($N = 24,099$ terms) we find the eigenvalue

$E = -2.90372\ 43770\ 34119\ 59831\ 11592\ 45194\ 40444\ 66969\ 25309\ \dots$

The spectral decomposition of the helium atom two-electron configuration in terms of hydrogenic orbitals

| 12 | 100 320 | 0 | 0 | 0.9828 |

Not 1.000 !

Why is this important?

$$\begin{aligned} U(Z) &= \int d^3 r d^3 r' |\varphi_{1s}(r)|^2 \frac{e^2}{|r - r'|} |\varphi_{1s}(r')|^2 \\ &= \frac{5}{4} Z \times 13.606 \text{ eV}, \end{aligned}$$

$$\varphi_{1s}(r) = \left(\frac{Z^3}{\pi a_0^3} \right)^{1/2} e^{-Zr/a_0}$$

Experimental values:

$$U_{\text{eff}}(1) = I - A = 12.86 \text{ eV} = U(1) - 4.15 \text{ eV} \quad (2a)$$

$$U_{\text{eff}}(2) = I_{II} - I_I = 29.92 \text{ eV} = U(2) - 4.10 \text{ eV}. \quad (2b)$$

4 eV \approx 46 000 K !

In essentially **all** the lattice models used to understand electron correlations in solids, the “playing field” is static (phonons are a different matter).

In He, when one electron is present, it occupies the 1s orbital:

When two electrons are present, in Hubbard-like models they (doubly) occupy the 1s orbital:

• For Hubbard model:

$$\psi(\vec{r}_1, \vec{r}_2) = \Phi_{1s}(\vec{r}_1)\Phi_{1s}(\vec{r}_2)$$

• For real atom

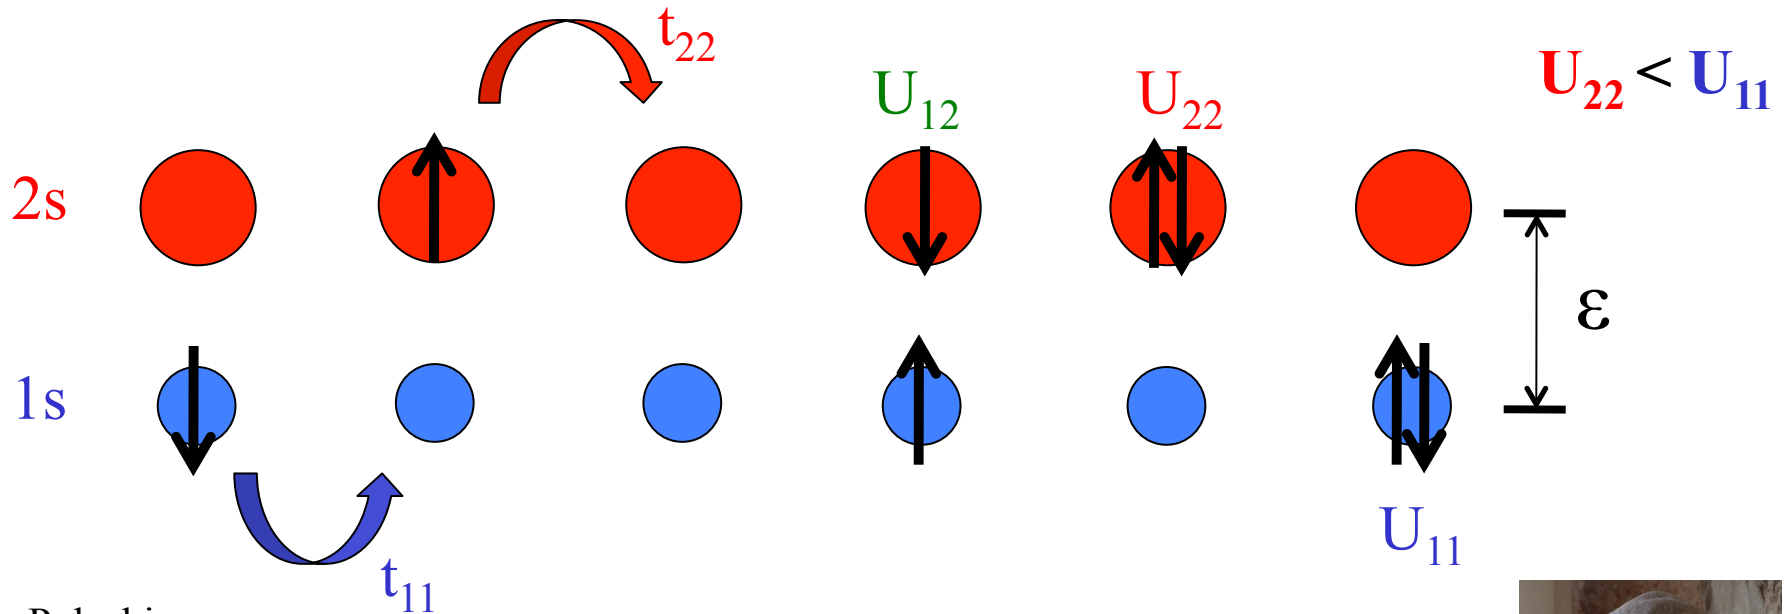

$$\psi(\vec{r}_1, \vec{r}_2) = \sum_{mn} c_{mn} \Phi_m(\vec{r}_1)\Phi_n(\vec{r}_2)$$

This is like what happens in general relativity; the presence of mass alters the underlying space-time structure.

This is like what happens in general relativity; the presence of mass alters the underlying space-time structure.

Here, the presence of a second electron alters the nature of the orbitals that model the conduction band.

Chris Polachic

Lindsay Forestell

Exact Diagonalizations (very small clusters!)

AND

Dynamical Mean Field Theory (DMFT)

FIGURE 4. Mean-field theory replaces a lattice model by a single site coupled to a self-consistent bath.

$$U_{eff} = E_0(N_e) + E_0(N_e - 2) - 2E_0(N_e - 1)$$

Lindsay Forestell

This is like what happens in general relativity; the presence of mass alters the underlying space-time structure.

Here, the presence of a second electron alters the nature of the orbitals that model the conduction band.

A simple way to model this:

hopping term

$$H_{DHB} = - \sum_{\langle i,j \rangle \sigma} t_{ij} (c_{i\sigma}^+ c_{j\sigma} + c_{j\sigma}^+ c_{i\sigma}) - \mu \sum_{i\sigma} n_{i\sigma} +$$

$$\sum_i (\omega_o \sigma_i^x + g \omega_o \sigma_i^z) + \sum_i (U - 2g \omega_o \sigma_i^z) n_{i\uparrow} n_{i\downarrow}$$

$$t_e = t \quad (\text{electron in an empty lattice})$$

Tf

$$a \quad t_h = t S^2 \quad (\text{electron in an almost full lattice})$$

where $S =$ Franck-Condon factor.

Dynamic Hubbard Model

J.E. Hirsch, PRB 65, 184502 (2002)

$$H_{\text{DHM}} = \sum_{\langle i,j \rangle \sigma} t_{ij} (c_{i\sigma}^\dagger c_{j\sigma} + c_{j\sigma}^\dagger c_{i\sigma}) - \mu \sum_{i,\sigma} n_{i\sigma} \\ + \sum_i (\omega_0 \sigma_i^x + g\omega_0 \sigma_i^z) + \sum_i (U - 2g\omega_0 \sigma_i^z) n_{i\uparrow} n_{i\downarrow}$$

Parameter

- t electron hopping
- U 'bare' electron-electron repulsion
- g electron-pseudospin coupling strength
- ω_0 energy (time) scale associated with pseudospin

How do we check this out? (i) effective model
(ii) exact diagonalizations
(iii) Dynamical Mean Field Theory

Pseudospin expectation values

G.H. Bach et al., PRB 82, 155122 (2010)

FIG. 12. (Color online) The spectral function for various energies, as shown, for (a) $n=0.2$ and (b) $n=1.8$. Here, we have used $U=1$, $g=1$, and $\omega_0=2$ (see pink curve in Fig. 9). The second last frame in each instance shows the spectral function at an energy corresponding to the Fermi level, and the weight under the peak at $\omega=0$ corresponds to the quasiparticle residue, z .

$$U=1, g=1, \omega_0 = 2$$

Optical conductivity

G.H. Bach et al., PRB 82, 155122 (2010)

See also G.H. Bach and F.M. PRB 85, 155134 (2012)

$$\sigma_1^{(3)}(\omega) = \frac{\pi e^2 t}{2\hbar^2} \left[S^2 \delta\left(\omega - \frac{2tS^2}{\hbar}\right) + 4S^2 \bar{S}^2 \frac{t}{\Omega_0} \delta\left(\omega - \frac{\Omega_0}{\hbar}\right) + \bar{S}^4 \frac{t}{\Omega_0} \delta\left(\omega - \frac{2\Omega_0}{\hbar}\right) \right]. \quad (29)$$

$$\sigma_1^{(1)}(\omega) = \frac{\pi e^2 t}{2\hbar^2} \delta(\omega - 2t/\hbar),$$

Dimer calculations

How do we measure this ?

Optical Sum Rule (Kubo)

$$\int_0^\infty d\nu \sigma_1(\nu) = \frac{\pi e^2}{\hbar^2} \frac{1}{N} \sum_k \left(\frac{\partial^2 \epsilon_k}{\partial k^2} \right) n_k$$

for all bands (or quadratic dispersion):

$$= \frac{\pi e^2 n}{2m} = \omega_P^2 / 8$$

for tight-binding band (with nearest neighbour hopping):

$$\frac{\partial^2 \epsilon_k}{\partial k^2} = -a^2 \epsilon_k$$

$$\int_0^\infty d\nu \sigma_1(\nu) = \frac{\pi e^2 a^2}{2\hbar^2} \langle -E_k \rangle$$

why is there temperature dependence
in the normal state ?

Answer:

- 1) $n_k \rightarrow f_k$ (Fermi-Dirac)
- 2) interactions

$$E_{kin} = 2 \sum \epsilon_k n_k$$

Note: Absolute value of kinetic energy decreases in the superconducting state. This is conventional behaviour

Summary

I've tried to make the case that the BCS pairing formalism gives an excellent description of the superconducting state
but...

The actual **mechanism** is an active subject of current interest for all superconductors

Key Points

What are the essential ingredients buried in the parameter μ^* ?

- (i) Maybe the Hubbard and Hubbard-like models don't really capture the essence of electron correlations in metals.
- (ii) The Dynamic Hubbard model tries to incorporate orbital relaxation --- the fact that orbitals expand, etc. when doubly occupied. Do these processes play an important role for superconductivity?

Moreover...

- We find a fundamental electron-hole asymmetry. This asymmetry is apparent in tunneling, and more indirectly through other probes.
- Pairing (requiring further study) results in **energy lowering through kinetic energy (not potential energy)**, as seen in several optical conductivity studies (Basov, van der Marel, Bontemps, Timusk, etc.)
